1. Abstract

Traditional robotic arms are controlled via joysticks or pre-programmed sequences methods that are non-intuitive and require prior technical training. This project presents the design and implementation of a 4-Degree-of-Freedom (4-DOF) Gesture-Controlled Robotic Arm using computer vision and an ESP32 microcontroller, enabling real-time intuitive control through natural hand gestures captured by a standard 2D webcam.

MediaPipe Hands detects 21 hand landmarks per frame at 30 FPS. Finger extension ratios are mathematically mapped to servo angles (0°–180°) for shoulder, elbow, wrist/turntable, and gripper joints. A 7 byte binary packet is transmitted wirelessly via TCP/Wi-Fi to the ESP32, which bridges the command to an Arduino Nano over UART. The Nano drives four servo motors (MG995 × 3 and SG90 × 1) using hardware PWM, achieving end-to-end latency under 100 ms. The system is fully built from low-cost components and 3D-printed structures, aligning with SDG 4, SDG 8, and SDG 9.

2. Literature Survey

Five peer-reviewed papers from IEEE and Springer proceedings (2021–2026) relevant to gesture-controlled robotics, embedded vision systems, and Wi-Fi-based servo control are surveyed below.

Year	Title of the Paper	Methodology / Approach	Key Findings	Limitations
2025	Gesture-Controlled Robotic Arm for Small Assembly Lines Angelidis & Bampis	RGB-D camera; ROS + MoveIt! IK; 7-DOF Panda cobot; 3-D skeletal hand model	High-precision assembly manipulation; full 3-D spatial awareness	Cost > $20,000; requires GPU + ROS; not portable to embedded systems
2023	Real-Time Hand Gesture Recognition for Robotic Arm — IEEE ICCCNT	MediaPipe Hands; CNN gesture classifier; Arduino serial link	94.7% accuracy; ~85 ms pipeline latency	Single hand only; fixed gesture vocabulary; no wireless link
2022	Vision-Based Robotic Arm Control with OpenCV Springer CCIS Vol. 1612	OpenCV Haar cascade + contour detection; 3-DOF arm via USB serial	Glove-free 2-D camera control proven feasible at low cost	Sensitive to lighting and background; no wireless link
2023	ESP32-Based IoT Robotic Arm with Wi-Fi Control IEEE TENSYMP	ESP32 TCP socket server; multi-channel PWM; web-dashboard interface	Sub-100 ms wireless latency; multi-servo simultaneous control confirmed	Web UI only not gesture-driven; no vision integration
2024	Human-Robot Interaction via Hand Landmark Tracking IEEE ICDCS	MediaPipe landmark-to-angle mapping; ESP32 PWM; UART 7-byte packet protocol	Finger-to-joint angle validated; operates without ROS or Linux	No smoothing filter; commercially sourced arm; single hand only

3. Methodology

(i) Block Diagram Hardware Framework

The system converts hand gestures into physical arm motion through seven sequential stages:

- Hand Gesture (Input): The user's hand posture is the sole control input.
- Camera Module: A 2-D USB webcam streams video at 30 FPS to the host PC.
- Gesture Processing (Python / OpenCV / MediaPipe): 21 hand landmarks detected per frame; finger extension ratios linearly mapped to target servo angles (0°–180°).
- TCP / Wi-Fi Communication: A 7-byte packet [0xFF, W, Sh, El, TT, Gr, 0xFE] is transmitted over a TCP socket (port 1234) to the ESP32's IP address.
- ESP32 (UART Bridge): Validates the packet and forwards bytes to the Arduino Nano via HardwareSerial2 (GPIO 16 / 17, 9600 baud).
- Arduino Nano (Servo Controller): Parses the 7-byte packet and writes constrained PWM angles to each servo pin via the Servo library.
- Robotic Arm (Output): Base, shoulder, elbow, and gripper joints articulate in real time to replicate the hand gesture.

4. Results

(i) CAD Model - Fusion 360 Simulation

The robotic arm was fully modelled in Fusion 360 (project: 3dPrinted_robotArm_step v2) before physical fabrication. The assembly includes a rotative base, ARM_1_L and ARM_2 link segments, three MG-995 servo mounts, one SG-92R gripper assembly, five precision bearings, and M3 base screws. Range-of-motion limits, servo fitment, and joint clearances were validated in simulation before STL export for 3D printing in PLA.

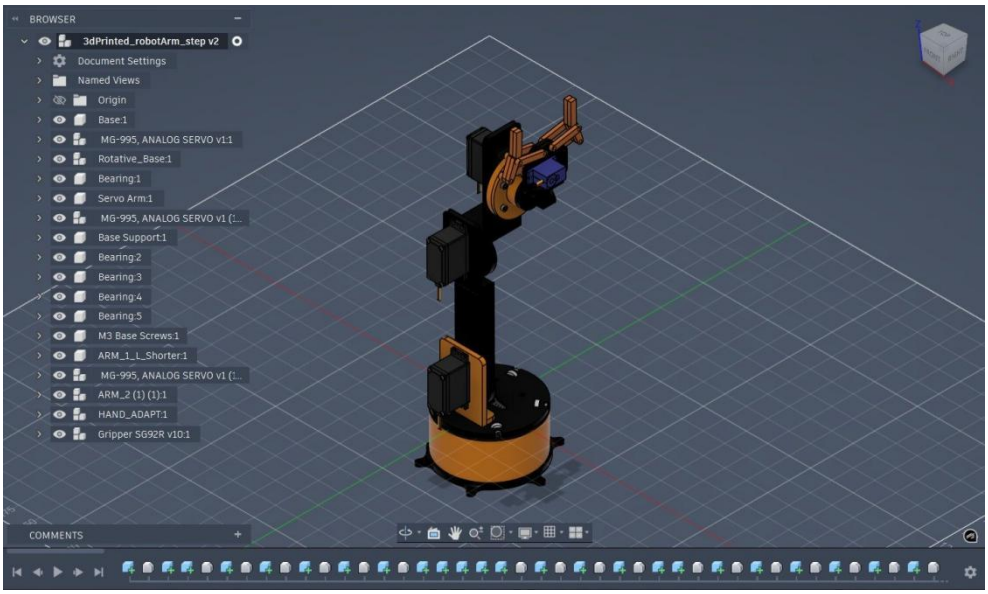

Figure 3: Fusion 360 CAD Model - 3D Printed Robotic Arm (3dPrinted_robotArm_step v2)

(ii) Hardware Prototype - Physical Assembly

The physical prototype was assembled with 3D-printed PLA structural components, three MG995 servo motors (shoulder, elbow, base turntable), and one SG90 micro servo (gripper). Servo signal wires route internally through the arm links to the Arduino Nano, which connects to the ESP32 over direct UART (GPIO 16/17). During testing all five joints responded accurately and simultaneously to hand gesture commands transmitted over Wi-Fi with measured end-to-end latency of 80–100 ms.

Figure 4: Hardware Prototype - Assembled 4-DOF Gesture-Controlled Robotic Arm

(iii) System Output - Gesture Recognition in Action

The following photographs capture real-time gesture recognition during live testing. The MediaPipe hand-tracking pipeline correctly classifies distinct finger configurations and transmits the corresponding servo commands to the robotic arm via Wi-Fi within the measured 80–100 ms end-to-end latency window.

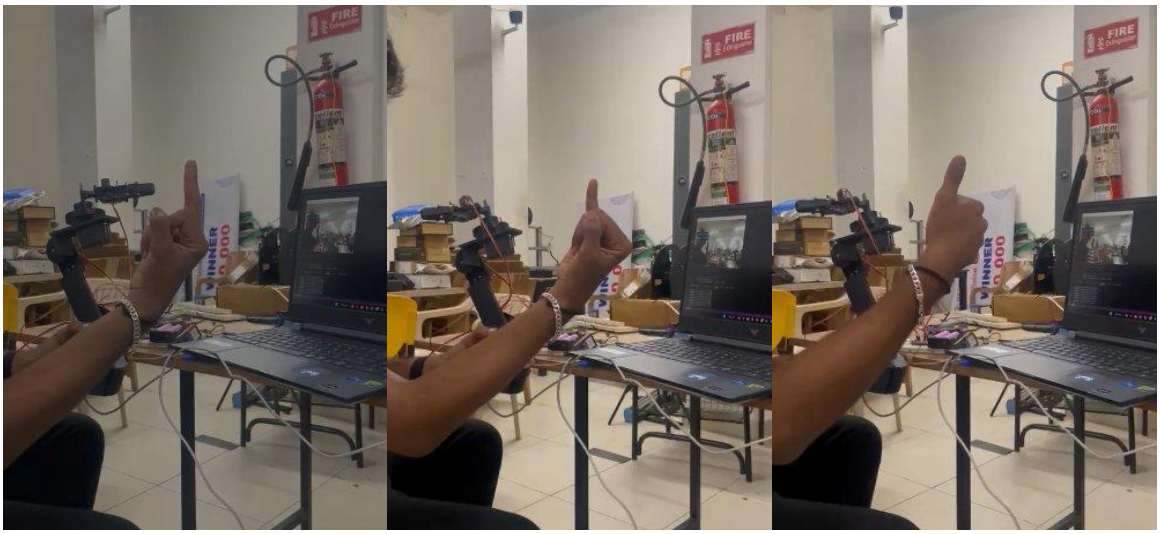

Figure 5: Live Gesture Recognition -Index-Up, Thumbs-Up, and Thumbs-Up (Side View) detected by MediaPipe and transmitted to the robotic arm

5. Conclusion and Future Work

This project successfully demonstrated a complete, end-to-end 4-DOF gesture-controlled robotic arm using computer vision (OpenCV + MediaPipe), a TCP/Wi-Fi communication layer (Python → ESP32), a UART bridge (ESP32 → Arduino Nano), and 3D-printed hardware. The system achieves intuitive, glove-free, controller-free arm control at under 100 ms latency at a cost well below comparable industrial platforms. By eliminating dependency on ROS, dedicated GPU workstations, or RGB-D sensors, the project is readily reproducible in academic and prototyping environments.

The project contributes to SDG 9 (low-cost robotic automation), SDG 8 (productivity through automation), and SDG 4 (affordable hands-on STEM education).

Future Work

- Deep Learning Gesture Recognition: Replace rule-based ratio mapping with CNN/LSTM for complex temporal gestures and improved robustness.
- Reinforcement Learning for Trajectory Optimisation: RL agents to minimise motion time and energy in pick-and-place tasks.
- Autonomous Pick-and-Place: Integrate YOLOv8 object detection for gesture-triggered fully autonomous task execution.
- Dual-Hand Bimanual Control: Extend mapping to both hands for coordinated multi-servo control.
- 6-DOF Mechanical Upgrade: Scale the 3D-printed structure to six degrees of freedom with an additional wrist-rotation joint.
